EXPERIMENT 9

AI FEATURES AND ANALYTICS (ZIA)

1. Aim

To explore the AI-assisted capabilities presented by Zoho Creator's Zia Build Agent and understand how AI assistance and application analytics may support a loan application management system.

2. Objectives

• Explore the Zia Build Agent in the existing Zoho Creator application.

• Review the capabilities described by the Build Agent.

• Test whether the Build Agent provides application-specific analysis.

• Identify how existing reports and dashboards can summarize loan application data.

• Document observed output and limitations without claiming unverified functionality.

3. Software and Application Details

Platform: Zoho Creator
AI feature: Zia Build Agent
Application: Loan Application & Pre-Screening Management
Form referenced: Loan_Application_Form
Existing analytics component: Loan_Application_Dashboard with "Loan Type Distribution – Pie Chart" (documented in Experiment 5; current chart values were not verified in this experiment).

4. Theory

Zia Build Agent is an AI-assisted interface in Zoho Creator. In the observed interface, it described its capabilities as building and configuring forms, fields, reports, pages, workflows, blueprints, app menus, themes, and permissions. It also stated that it cannot delete components. This is the agent's displayed capability summary, not proof that every capability is enabled or successfully tested in the account.

Reports and dashboards can summarize application records. In a loan application system, grouping records by loan type can help show the distribution of applications. Chart values should be compared with the underlying report before conclusions are drawn.

5. Procedure

• Opened the existing Loan Application & Pre-Screening Management application.

• Opened the Zia Build Agent interface.

• Asked the agent to describe its capabilities.

• Submitted a prompt asking it to identify existing form, report, and dashboard components and propose an analytics page grouped by loan type and application count, without modifying anything.

• Observed that it returned the same generic capability description instead of application-specific analysis.

• Submitted a second, more specific prompt asking it to inspect Loan_Application_Form and identify its fields without making changes.

• Observed the same generic response again. No proposed changes were applied.

6. Test Cases and Observations

Test	Expected result	Observed result
Access Build Agent	Interface opens	Passed: Build Agent interface was visible.
Review capabilities	Agent describes supported tasks	It listed forms, fields, reports, pages, workflows, blueprints, menus, themes, and permissions; it stated it cannot delete components.

Test	Expected result	Observed result
Application-specific analysis	Identifies actual components and fields	Not demonstrated: both prompts produced the same generic description.
Dashboard analytics	Chart can be compared with report data	Not verified here. The dashboard and pie chart were documented in Experiment 5; live values were not checked.

7. Result

The Zia Build Agent was accessible and displayed a general description of its capabilities. It did not provide application-specific component or field analysis in the two prompts tested. Therefore, the AI-assisted analysis task was not demonstrated successfully. Dashboard chart values and consistency with the underlying report were not verified during this experiment.

8. Conclusion

This experiment introduced the Zia Build Agent and examined its displayed capability summary. Access to the agent did not result in application-specific analysis during this test. The repeated generic response was recorded as an observed limitation. No unsupported claim was made that Zia generated an analytics page or analyzed application data.

9. Evidence

The screenshots below show the Build Agent prompts and its generic response. They are included as evidence of the test performed.

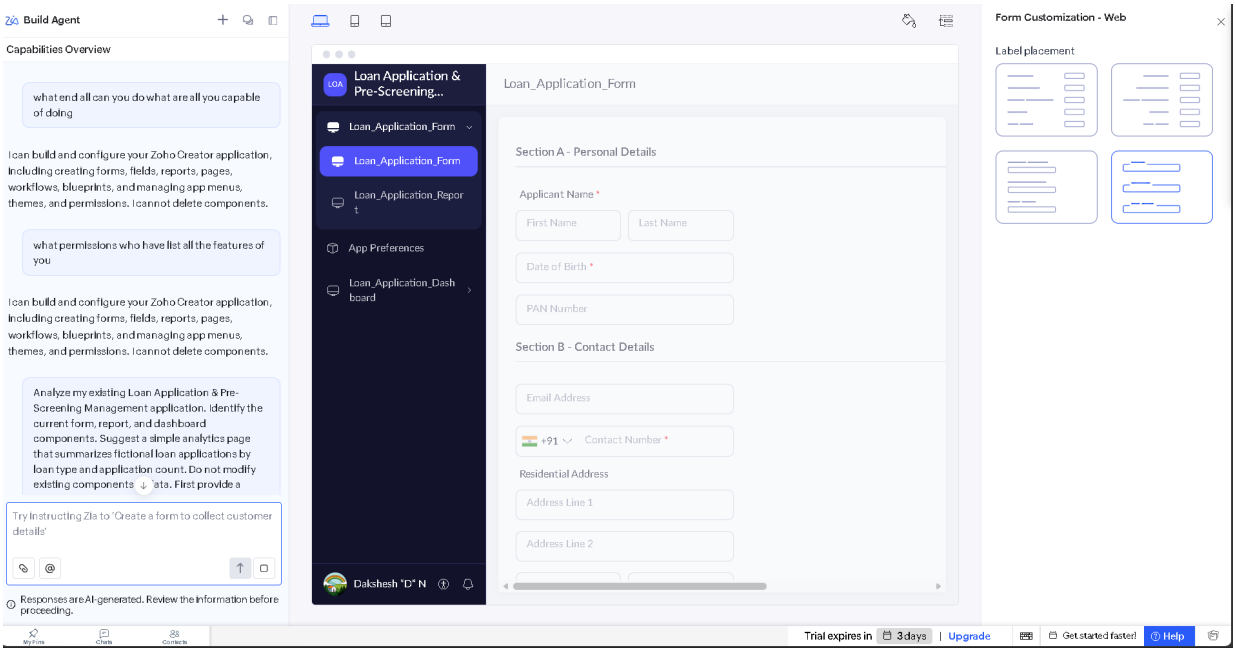

Figure 9.1 — Build Agent interface and first analysis prompt.
